

# Chapter 6

## Advanced Encryption Standard

# Outline

- AES: introduction
- AES parameters
- AES Encryption
  - Overview
  - Data structures
  - Round functions
  - Key Expansion
- Decryption
- Implementation

Using slides from “Understanding Cryptography, by Christof Paar and Jan Pelzl, [www.crypto-textbook.com](http://www.crypto-textbook.com)”

# AES: introduction

## ■ Some Basic Facts

- AES is the most widely used symmetric cipher today
- The algorithm for AES was chosen by the US *National Institute of Standards and Technology* (NIST) in a multi-year selection process
- The requirements for all AES candidate submissions were:
  - Block cipher with **128-bit block size**
  - **Three supported key lengths**: 128, 192 and 256 bit
  - Security relative to other submitted algorithms
  - **Efficiency** in software and hardware

Rijndael (pronounced **rain-dahl**)  
is named after its two creators:  
Vincent **Rijmen** and Joan **Daemen**

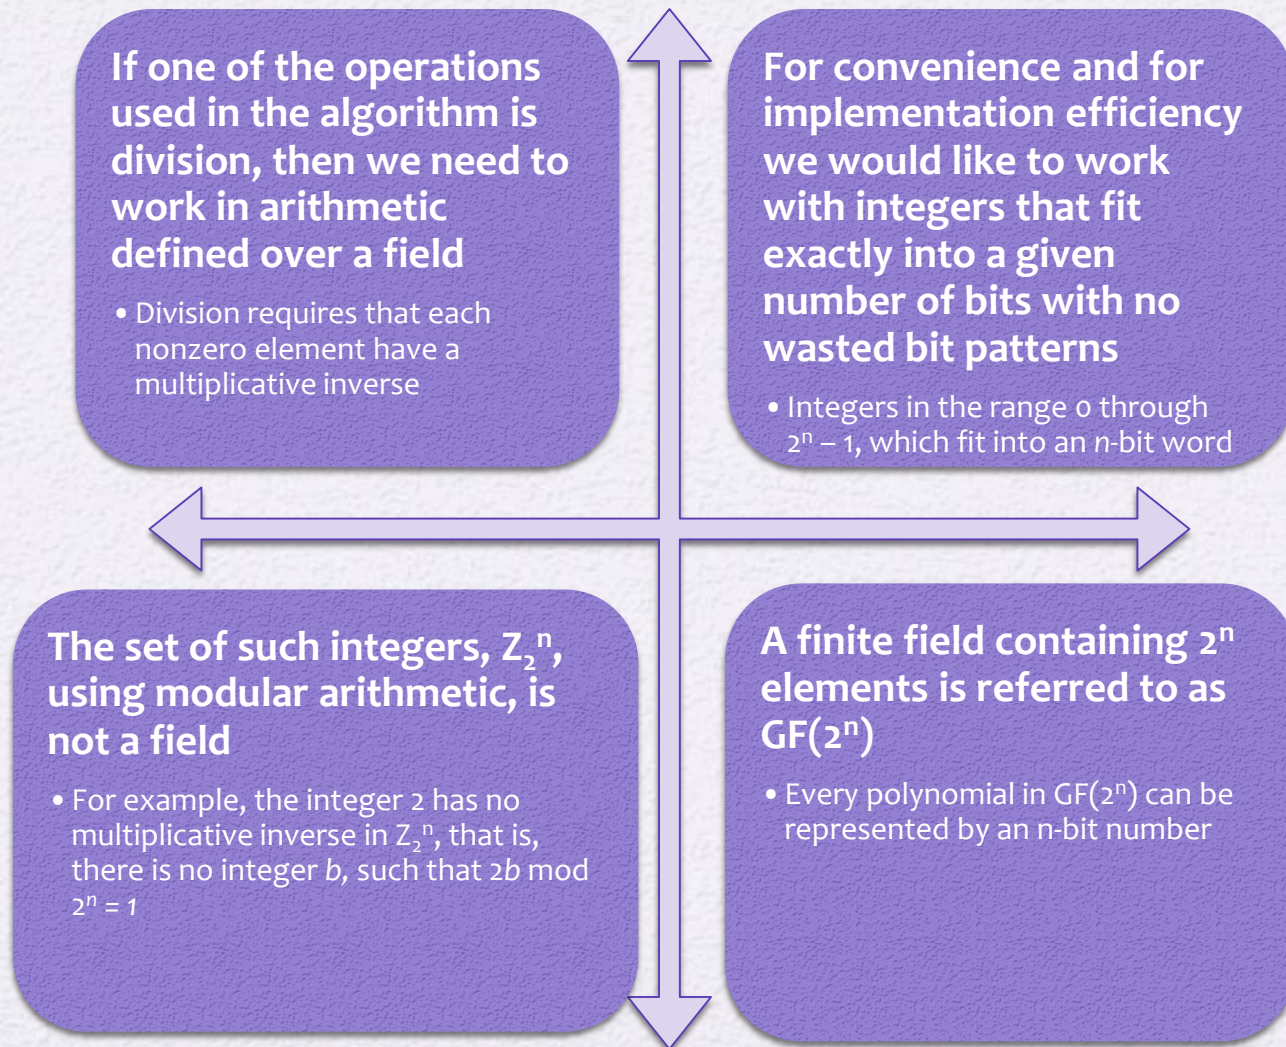

## ■ Chronology of the AES Selection

- The need for a new block cipher announced by NIST in January, 1997
- 15 candidates algorithms accepted in August, 1998
- 5 finalists announced in August, 1999:
  - *Mars* – IBM Corporation
  - *RC6* – RSA Laboratories
  - *Rijndael* – J. Daemen & V. Rijmen
  - *Serpent* – Eli Biham et al.
  - *Twofish* – B. Schneier et al.
- In October 2000, *Rijndael* was chosen as the AES
- AES was formally approved as a US federal standard in November 2001

# Finite Field Arithmetic

- In the Advanced Encryption Standard (AES) all operations are performed on 8-bit bytes
  - i.e. byte operations
- The arithmetic operations of addition, multiplication, and division are performed over the finite field  $GF(2^8)$ 
  - A field is a set in which we can do addition, subtraction, multiplication, and division without leaving the set
  - Division is defined with the following rule:
    - $a/b = a(b^{-1})$
- An example of a finite field (one with a finite number of elements) is the set  $Z_p$  consisting of all the integers  $\{0, 1, \dots, p-1\}$ , where  $p$  is a prime number and in which arithmetic is carried out modulo  $p$

# Finite Field Arithmetic: review

# AES vs. DES

|                  | DES  | AES  |
|------------------|--|--|
| Structure        | Feistel  | permutation-substitution-network                   |
| Key Size (s)     | 56 bits  | 128 , 192 or 256 bits                              |
| Number of Rounds | 16   | 10, 12, 14   |
| Block size       | 64 bits  | 128 bits   |
| Security         | Proven inadequate<br>Breakable<br>Small key size | Considered secure<br>Unbreakable<br>Large key size |

**AES Has Larger Block Size, Larger Key Size and Better Round Functions**

# AES Parameters

- Structure: permutation-substitution-network (PSN)
- Key sizes: 128 , 192 or 256 bits
  - Number of rounds (depends on key size): 10, 12 or 14
  - Key is expanded to:  $[\text{Number\_of\_Rounds}+1] \times 4$  words
- Block size (input and output): 128 bits
- Our discussion will focus on 128-bit key (i.e. 10-round algorithm)

|   | 128-bit key<br>10 Rounds | 192-bit key<br>12 Rounds | 256-bit key<br>14 Rounds |
|---|--------------------------|--------------------------|--------------------------|
| Key Size (words/bytes/bits)             | 4/16/128                 | 6/24/192                 | 8/32/256                 |
| Plaintext Block Size (words/bytes/bits) | 4/16/128                 | 4/16/128                 | 4/16/128                 |
| Number of Rounds                        | 10                       | 12                       | 14                       |
| Round Key Size (words/bytes/bits)       | 4/16/128                 | 4/16/128                 | 4/16/128                 |
| Expanded Key Size (words/bytes)         | 44/176                   | 52/208                   | 60/240                   |

# AES Overview

- Key expansions
- $N$  rounds (+initial transformation)
  - $N$  is 10, 12 or 14
- Round includes four stages: 1 permutation and 3 substitutions.
  - Substitute bytes: Uses an S-box to perform a byte-by-byte substitution of the block
  - ShiftRows: A simple permutation
  - MixColumns: A substitution that makes use of arithmetic over  $GF(2^8)$
  - AddRoundKey: A simple bitwise XOR of the current block with a portion of the expanded key
- Once it is established that all four stages are reversible.

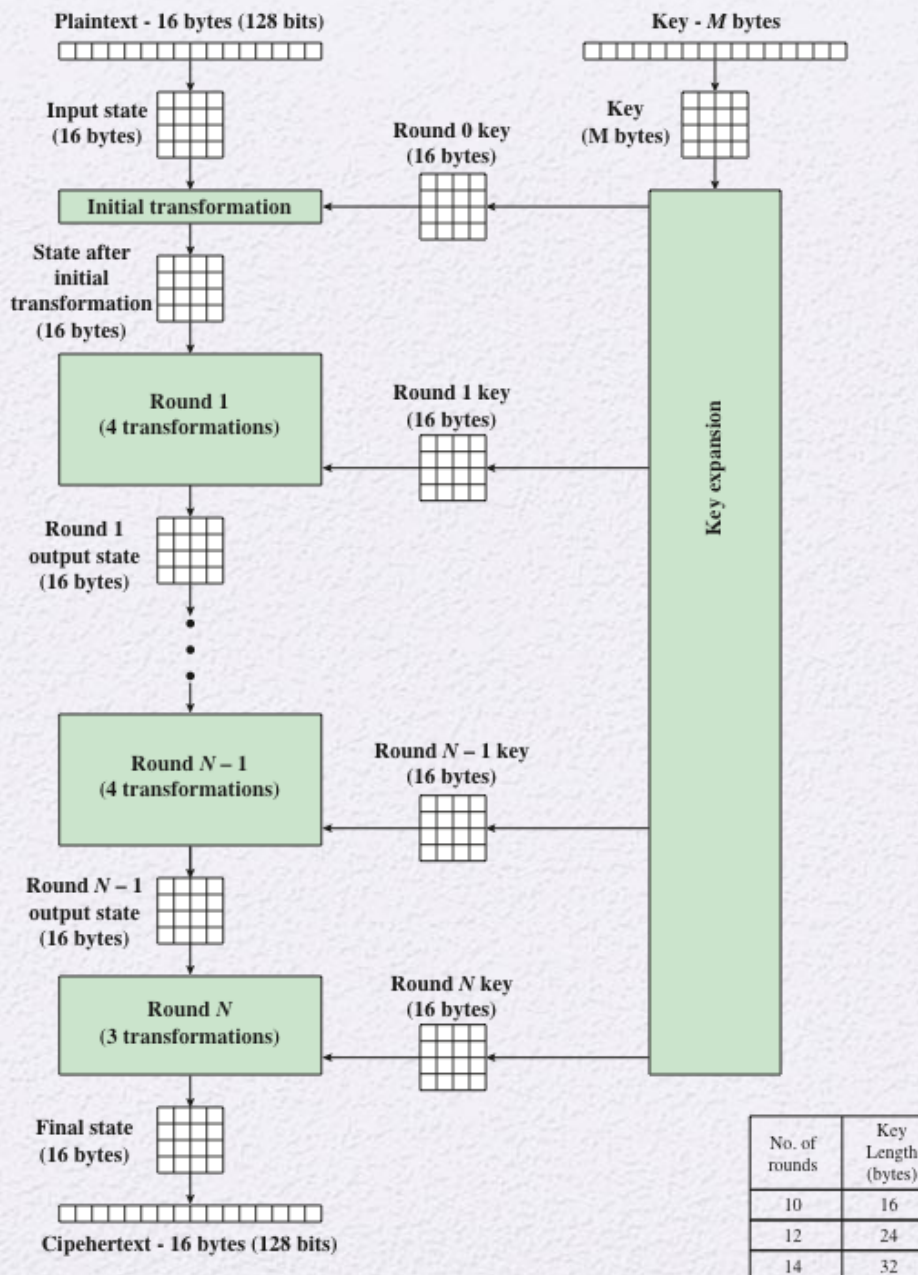

Figure 6.1 AES Encryption Process

# Data Structure: Blocks and States

- Input and outputs are 128-bit blocks of data.
- Algorithm is based on state array of 4x4 bytes.
- Input is copied to state array, then processed.
- Final state array is copied to output.
- Key is expanded to linear array of 32-bit (4-byte) words.

(a) Input, state array, and output

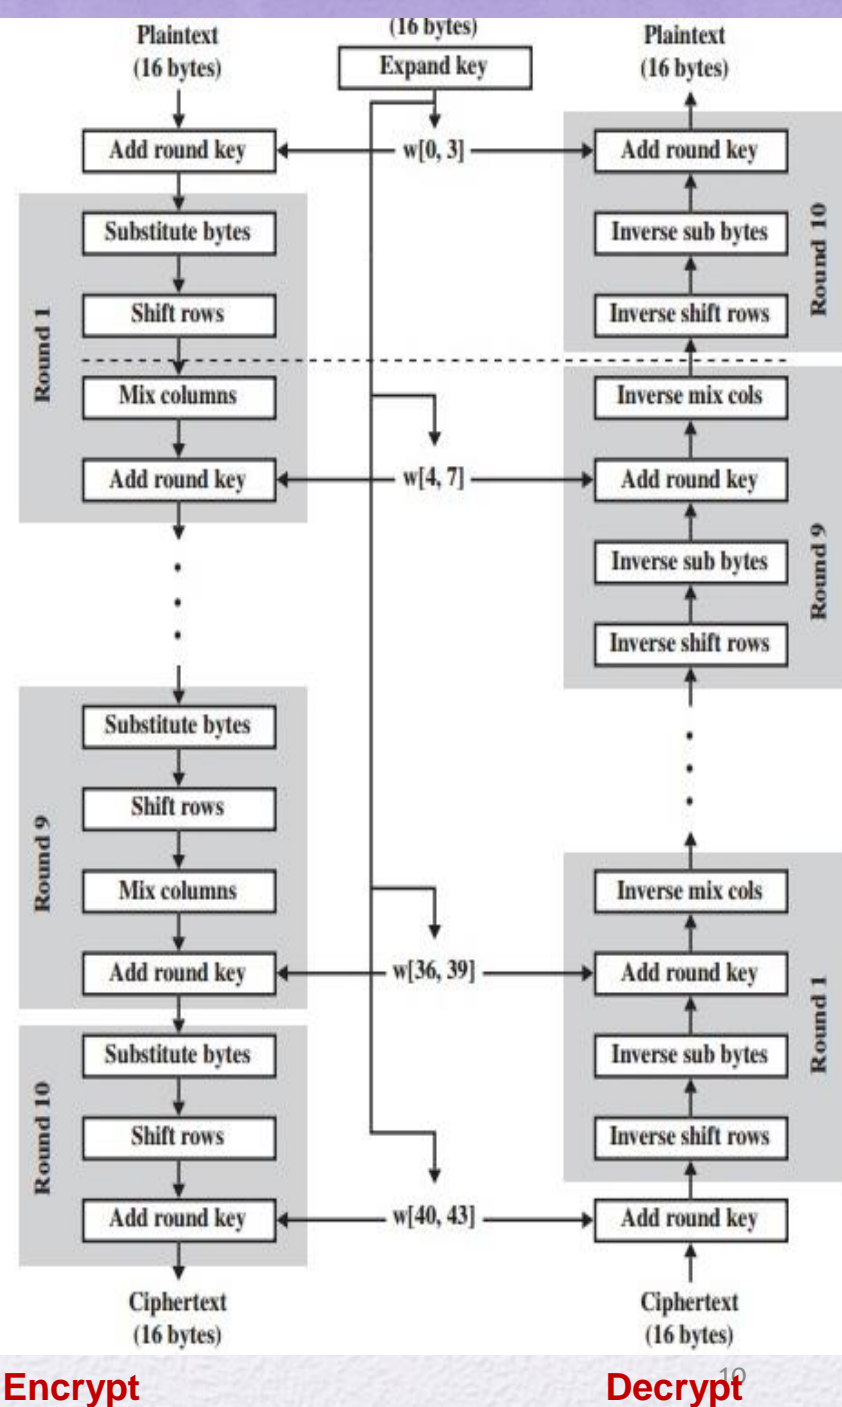

(b) Key and expanded key

**Data Structures: (a) input/output/state array (b) key and expanded key**

# Encryption/Decryption

- AES is **reversible**
- Decrypt reverses steps of encryption

Last round:  
No Mix Columns

# AES Round-Transformation Functions

- There are 4 Round Transformation Functions:
  1. Substitute Bytes (**SubBytes**) Transformation
    - uses an S-box to perform a byte-by-byte substitution of the block
  2. **ShiftRows** Transformation
    - a simple permutation
  3. **MixColumns** Transformation
    - a substitution that makes use of arithmetic over  $GF(2^8)$
  4. **AddRoundKey** Transformation
    - a simple bitwise XOR of the current block with a portion of the expanded key
- All functions has two flavors:
  - FORWARD TRANSFORMATION (for encryption)
  - INVERSE TRANSFORMATION (for decryption)

# S-Box Rationale

- The S-box is designed to be resistant to known cryptanalytic attacks
- The Rijndael developers sought a design that has a low correlation between input bits and output bits and the property that the output is not a linear mathematical function of the input
- The nonlinearity is due to the use of the multiplicative inverse

# Shift Row Rationale

- More substantial than it may first appear
- The State, as well as the cipher input and output, is treated as an array of four 4-byte columns
- On encryption, the first 4 bytes of the plaintext are copied to the first column of State, and so on
- The round key is applied to State column by column
  - Thus, a row shift moves an individual byte from one column to another, which is a linear distance of a multiple of 4 bytes
- Transformation ensures that the 4 bytes of one column are spread out to four different columns

# Mix Columns Rationale

- Coefficients of a matrix based on a linear code with maximal distance between code words ensures a good mixing among the bytes of each column
- The mix column transformation combined with the shift row transformation ensures that after a few rounds all output bits depend on all input bits

| 87 | F2 | 4D | 97 |
| EC | 6E | 4C | 90 |
| 4A | C3 | 46 | E7 |
| 8C | D8 | 95 | A6 |

**S-box is designed to have following properties:**

- Low correlation between input bits and output bits
- Output is not a linear mathematical function of input
- No self-inverse.
  - Example :  $S(a) \neq IS(a)$
- Invertible.
  - Example:  $IS[S(a)] = a$

# S-box Generation

- How to generate S-box
- How  $S(C2_{\text{HEX}}) = 25_{\text{HEX}}$ ?
- Computation is done in two stages:
  - $GF(2^8)$  inverse
  - Affine mapping
- Example: let us compute  $S(C2)$ 
  - $B' = F2_{\text{HEX}}$
  - $B = 25_{\text{HEX}}$

$$\begin{pmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \\ b_5 \\ b_6 \\ b_7 \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} b'_0 \\ b'_1 \\ b'_2 \\ b'_3 \\ b'_4 \\ b'_5 \\ b'_6 \\ b'_7 \end{pmatrix} + \begin{pmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 0 \end{pmatrix} \pmod{2}$$

# 2. ShiftRows Transformation

- ShiftRows performs left rotations on the bytes of each row as follows:
  - First row: nothing
  - Second row: rotate-left(1) ; **note: rotate-left(1)  $\equiv$  rotate-right(3)**
  - Third row: rotate-left(2) ; **note: rotate-left(2)  $\equiv$  rotate-right(2)**
  - Fourth row: rotate-left(3) ; **note: rotate-left(3)  $\equiv$  rotate-right(1)**
- So, ShiftRows moves an individual byte from one column to another.

## Example

|    |    |    |    |
|----|----|----|----|
| 87 | F2 | 4D | 97 |
| EC | 6E | 4C | 90 |
| 4A | C3 | 46 | E7 |
| 8C | D8 | 95 | A6 |

→

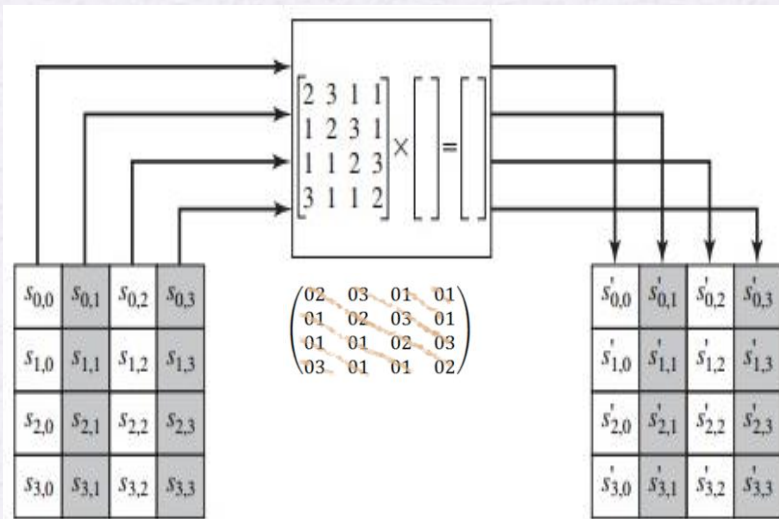

|    |    |    |    |
|----|----|----|----|
| 87 | F2 | 4D | 97 |
| 6E | 4C | 90 | EC |
| 46 | E7 | 4A | C3 |
| A6 | 8C | D8 | 95 |

# 3. MixColumns

## Example

- MixColumns, operates on each column individually.
- Each byte of a column is mapped into a new value that is a function of all four bytes in that column.

$$\begin{aligned}
 s'_{0,j} &= (2 \cdot s_{0,j}) \oplus (3 \cdot s_{1,j}) \oplus s_{2,j} \oplus s_{3,j} \\
 s'_{1,j} &= s_{0,j} \oplus (2 \cdot s_{1,j}) \oplus (3 \cdot s_{2,j}) \oplus s_{3,j} \\
 s'_{2,j} &= s_{0,j} \oplus s_{1,j} \oplus (2 \cdot s_{2,j}) \oplus (3 \cdot s_{3,j}) \\
 s'_{3,j} &= (3 \cdot s_{0,j}) \oplus s_{1,j} \oplus s_{2,j} \oplus (2 \cdot s_{3,j})
 \end{aligned}$$

|    |    |    |    |
|----|----|----|----|
| 87 | F2 | 4D | 97 |
| 6E | 4C | 90 | EC |
| 46 | E7 | 4A | C3 |
| A6 | 8C | D8 | 95 |

$$\begin{pmatrix} 47 \\ 37 \\ 94 \\ ED \end{pmatrix} = \begin{pmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{pmatrix} \cdot \begin{pmatrix} 87 \\ 6E \\ 46 \\ A6 \end{pmatrix}$$

$$\begin{aligned}
 &((02) \cdot \{87\}) \oplus ((03) \cdot \{6E\}) \oplus \{46\} \oplus \{A6\} = \{47\} \\
 &\{87\} \oplus ((02) \cdot \{6E\}) \oplus ((03) \cdot \{46\}) \oplus \{A6\} = \{37\} \\
 &\{87\} \oplus \{6E\} \oplus ((02) \cdot \{46\}) \oplus ((03) \cdot \{A6\}) = \{94\} \\
 &((03) \cdot \{87\}) \oplus \{6E\} \oplus \{46\} \oplus ((02) \cdot \{A6\}) = \{ED\}
 \end{aligned}$$

For the first equation, we have  $\{02\} \cdot \{87\} = (0000\ 1110) \oplus (0001\ 1011) = (0001\ 0101)$  and  $\{03\} \cdot \{6E\} = \{6E\} \oplus (\{02\} \cdot \{6E\}) = (0110\ 1110) \oplus (1101\ 1100) = (1011\ 0010)$ . Then,

$$\begin{aligned}
 \{02\} \cdot \{87\} &= 0001\ 0101 \\
 \{03\} \cdot \{6E\} &= 1011\ 0010 \\
 \{46\} &= 0100\ 0110 \\
 \{A6\} &= 1010\ 0110 \\
 0100\ 0111 &= \{47\}
 \end{aligned}$$

# MixColumns Computations

- Computations follows  $GF(2^8)$
- For results that have more than 8 bits ( i.e.,  $x^8$  or larger), use irreducible polynomial:
  - $x^8 + x^4 + x^3 + x + 1$
  - Which maps to:  $11B_{\text{HEX}}$

$$\{02\} \bullet \{87\} = \{15\}$$

$\{02\}$  corresponds to :  $f_1(x) = x$

$\{87\}$  corresponds to :  $f_2(x) = x^7 + x^2 + x + 1$

$$\{02\} \bullet \{87\} = f_1(x) \bullet f_2(x) = x^8 + x^3 + x^2 + x$$

$$f_1(x) \bullet f_2(x) \bmod(m(x)) = x^4 + x^2 + 1 = \{15\}$$

$$\begin{array}{rcl} \{02\} \bullet \{87\} & = & 0001 \ 0101 \\ \{03\} \bullet \{6E\} & = & 1011 \ 0010 \\ \{46\} & = & 0100 \ 0110 \\ \{A6\} & = & \underline{1010 \ 0110} \\ & & 0100 \ 0111 = \{47\} \end{array}$$

$$\begin{array}{rcl} 1000 \ 0111 & \{87\} \\ 0000 \ 0010 & \{02\} \\ \hline 1 \ 0000 \ 1110 & \text{result} \\ 1 \ 0001 \ 1011 & \text{mod } (11B) \\ \hline 0 \ 0001 \ 0101 & \{15\} \end{array}$$

$$\begin{array}{rcl} 0110 \ 1110 & \{6E\} \\ 0000 \ 0011 & \{03\} \\ \hline 1011 \ 0010 & \{B2\} \end{array}$$

# Review of $FG(2^8)$ Mathematics

- AES uses special polynomials in  $GF(2^8)$

| Operation                                | Description   | Example  |
|--|---|--|
| Addition                                 | bitwise XOR   |  |
| Multip. by 02:<br>$\{02\} \bullet \{B\}$ | <ul style="list-style-type: none"> <li>1-bit left shift</li> <li>Followed by a conditional bitwise XOR with (0001 1011) if the leftmost bit of the original value (prior to the shift) is 1.</li> </ul> | $\{02\} \bullet \{87\}$<br>$= (0000\ 1110) \oplus (0001\ 1011)$<br>$= (0001\ 0101)$<br>$= \{15\}$  |
| $\{03\} \bullet \{B\}$                   | $\{03\} \bullet \{B\} = \{B\} \oplus (\{02\} \bullet \{B\})$  | $\{03\} \bullet \{6E\}$<br>$= \{6E\} \oplus (\{02\} \bullet \{6E\})$<br>$= (0110\ 1110) \oplus (1101\ 1100)$<br>$= (1011\ 0010)$<br>$= \{B2\}$ |

# Explaining Calculation in Finite Field $GF(2^8)$

- AES uses arithmetic in finite field  $GF(2^8)$ 
  - Polynomial based math.
  - Polynomial are expressed as binary
    - $m(x) = x^8 + x^4 + x^3 + x + 1$  (expression)
    - $m(x) = 1\ 0001\ 1011 = 11B_{\text{HEX}}$  (binary/Hex)
  - Add/Sub : XOR operation
  - Multiply : AND operation
- In  $GF(2^8)$  field:
  - Additions and multiplications are performed on polynomials
  - Polynomials are multiplied /added,
  - Then divided by  $m(x)$  to compute remainder (i.e., modulus operation)
    - $m(x) = x^8 + x^4 + x^3 + x + 1$

# MixColumns: Encryption and Decryption

- Encryption:

$$\text{MixColumn}(B) = C$$

$$\begin{pmatrix} C_0 \\ C_1 \\ C_2 \\ C_3 \end{pmatrix} = \begin{pmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{pmatrix} \begin{pmatrix} B_0 \\ B_5 \\ B_{10} \\ B_{15} \end{pmatrix}$$

- Decryption:

$$\text{InverseMixColumn}(C) = B$$

$$\begin{pmatrix} B_0 \\ B_1 \\ B_2 \\ B_3 \end{pmatrix} = \begin{pmatrix} 0E & 0B & 0D & 09 \\ 09 & 0E & 0B & 0D \\ 0D & 09 & 0E & 0B \\ 0B & 0D & 09 & 0E \end{pmatrix} \begin{pmatrix} C_0 \\ C_1 \\ C_2 \\ C_3 \end{pmatrix}$$

# MixColumns: Encryption and Decryption

## • Encryption

|    |    |    |    |
|----|----|----|----|

# MixColumns: One Issue You Should Know

- If all state bytes are the same, then applying MixColumns step will produce the same state!
- Why? Because XOR operation cancels identical terms:
  - $\{03\} \cdot \{A9\}$  cancels  $\{02\} \cdot \{A9\}$  and  $\{01\} \cdot \{A9\}$
  - there is one term left  $\{01\} \cdot \{A9\} = \{A9\}$

# 4. AddRoundKey Transformation

- AddRoundKey is byte-level XOR-ing between state array and round key

**128-bit state**

|    |    |    |    |
|----|----|----|----|
| 47 | 40 | A3 | 4C |
| 37 | D4 | 70 | 9F |
| 94 | E4 | 3A | 42 |
| ED | A5 | A6 | BC |

$\oplus$

**128-bit key**

|    |    |    |    |
|----|----|----|----|
| AC | 19 | 28 | 57 |
| 77 | FA | D1 | 5C |
| 66 | DC | 29 | 00 |
| F3 | 21 | 41 | 6A |

=

|    |    |    |    |
|----|----|----|----|
| EB | 59 | 8B | 1B |
| 40 | 2E | A1 | C3 |
| F2 | 38 | 13 | 42 |
| 1E | 84 | E7 | D6 |

# AddRoundKey Transformation

- The 128 bits of State are bitwise XORed with the 128 bits of the round key
- Operation is viewed as a columnwise operation between the 4 bytes of a State column and one word of the round key
  - Can also be viewed as a byte-level operation

## Rationale:

Is as simple as possible and affects every bit of State

The complexity of the round key expansion plus the complexity of the other stages of AES ensure security

# AES Key Expansion

- Takes as input a four-word (16 byte) key and produces a linear array of 44 words (176) bytes
  - This is sufficient to provide a four-word round key for the initial AddRoundKey stage and each of the 10 rounds of the cipher
- Key is copied into the first four words of the expanded key
  - The remainder of the expanded key is filled in four words at a time
- Each added word  $w[i]$  depends on the immediately preceding word,  $w[i - 1]$ , and the word four positions back,  $w[i - 4]$ 
  - In three out of four cases a simple XOR is used
  - For a word whose position in the  $w$  array is a multiple of 4, a more complex function is used

# Key Expansion Rationale

- The Rijndael developers designed the expansion key algorithm to be resistant to known cryptanalytic attacks
- Inclusion of a round-dependent round constant eliminates the symmetry between the ways in which round keys are generated in different rounds

The specific criteria that were used are:

- Knowledge of a part of the cipher key or round key does not enable calculation of many other round-key bits
- An invertible transformation
- Speed on a wide range of processors
- Usage of round constants to eliminate symmetries
- Diffusion of cipher key differences into the round keys
- Enough nonlinearity to prohibit the full determination of round key differences from cipher key differences only
- Simplicity of description

# Key Expansion

- The AES key expansion algorithm takes as **input** a four-word (16-byte) key and **outputs** a linear array of 44 words (176 bytes).
- This is sufficient to provide a four-word round key for the initial AddRoundKey stage and each of the 10 rounds of the cipher.

```
KeyExpansion (byte key[16], word w[44])
{
    word temp
    for (i = 0; i < 4; i++)    w[i] = (key[4*i], key[4*i+1],
                                     key[4*i+2],
                                     key[4*i+3]);

    for (i = 4; i < 44; i++)
    {
        temp = w[i - 1];
        if (i mod 4 == 0)    temp = SubWord (RotWord (temp))
                               ⊕ Rcon[i/4];

        w[i] = w[i-4] ⊕ temp
    }
}
```

# Encryption VS Decryption

- AES decryption cipher is not identical to the encryption cipher
  - The sequence of transformations differs although the form of the key schedules is the same
  - Has the disadvantage that two separate software or firmware modules are needed for applications that require both encryption and decryption

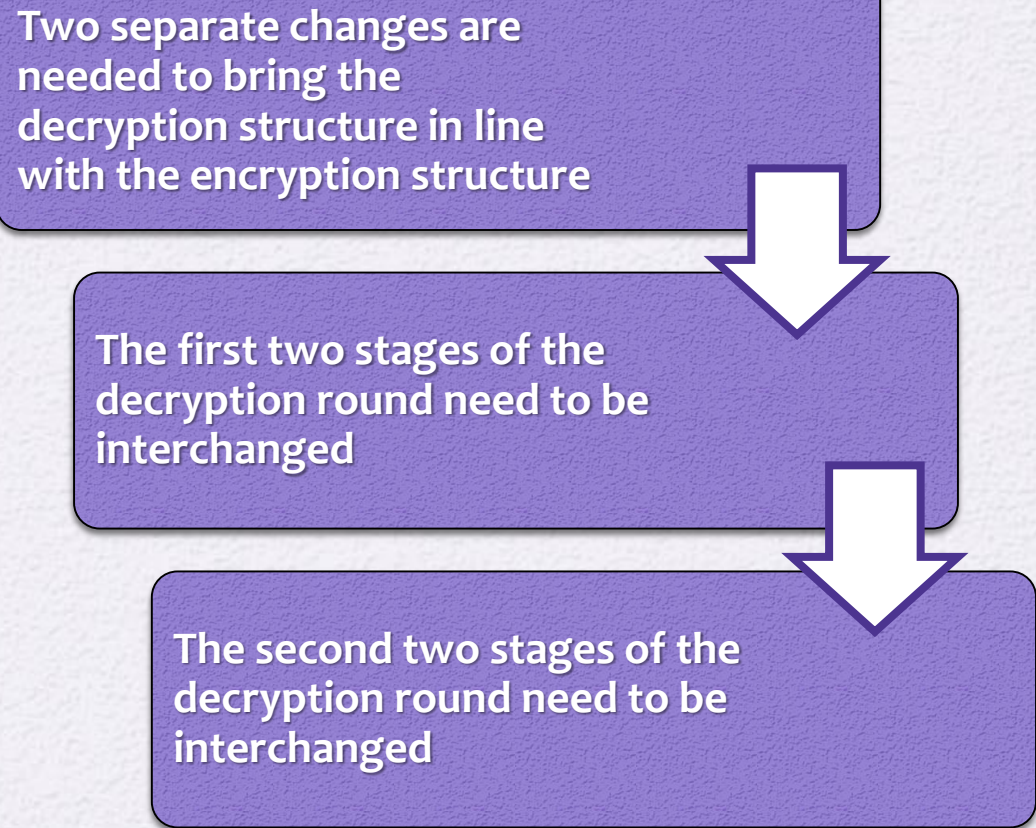

# Decryption: Equivalent Inverse Cipher

- AES decryption cipher is not identical to the encryption cipher
  - The sequence of transformations differs although the form of the key schedules is the same
  - Has the disadvantage that two separate software or firmware modules are needed for applications that require both encryption and decryption

Two separate changes are needed to bring the decryption structure in line with the encryption structure

```
graph TD; A[Two separate changes are needed to bring the decryption structure in line with the encryption structure] --> B[The first two stages of the decryption round need to be interchanged]; B --> C[The second two stages of the decryption round need to be interchanged];
```

The first two stages of the decryption round need to be interchanged

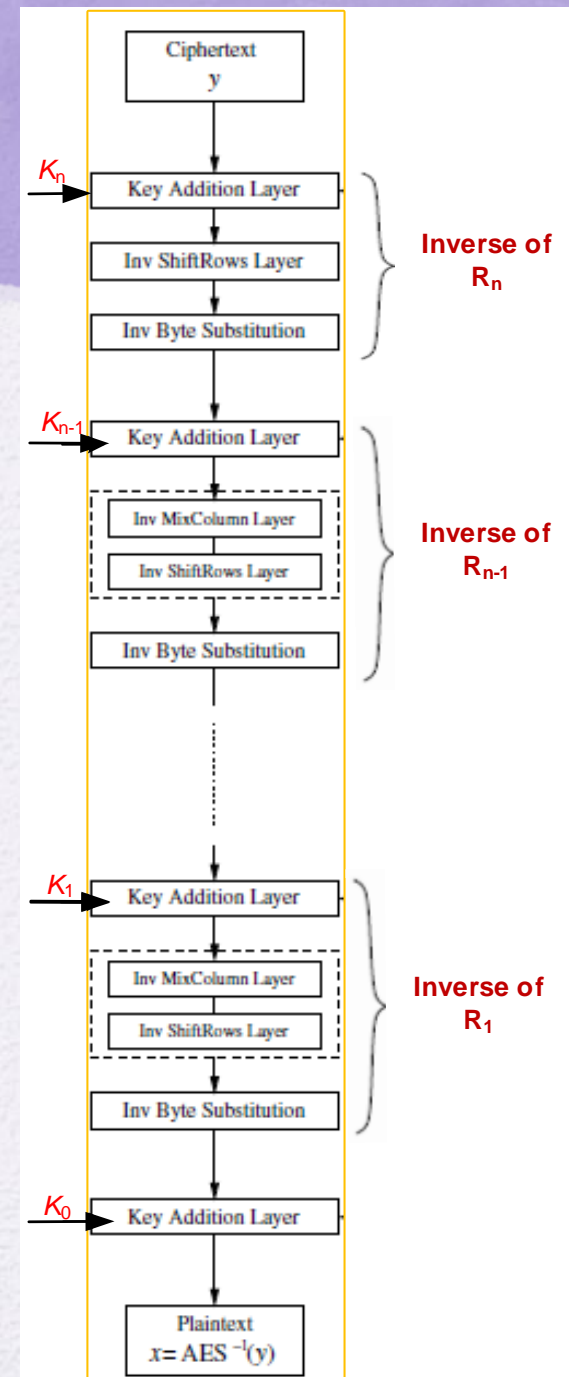

The second two stages of the decryption round need to be interchanged

# Interchanging InvShiftRows and InvSubBytes

- InvShiftRows *affects the sequence of bytes in State but does not alter byte contents and does not depend on byte contents to perform its transformation*
- InvSubBytes *affects the contents of bytes in State but does not alter byte sequence and does not depend on byte sequence to perform its transformation*

Thus, these two operations commute and can be interchanged

# Interchanging AddRoundKey and InvMixColumns

The transformations AddRoundKey and InvMixColumns do not alter the sequence of bytes in State

If we view the key as a sequence of words, then both AddRoundKey and InvMixColumns operate on State one column at a time

These two operations are linear with respect to the column input

# AES Implementation Aspects

- AES can be implemented very efficiently on an 8-bit processor
- AddRoundKey is a bitwise XOR operation
- ShiftRows is a simple byte-shifting operation
- SubBytes operates at the byte level and only requires a table of 256 bytes
- MixColumns requires matrix multiplication in the field  $GF(2^8)$ , which means that all operations are carried out on bytes

# Implementation Aspects

- Can efficiently implement on a 32-bit processor
  - Redefine steps to use 32-bit words
  - Can precompute 4 tables of 256-words
  - Then each column in each round can be computed using 4 table lookups + 4 XORs
  - At a cost of 4Kb to store tables
- Designers believe this very efficient implementation was a key factor in its selection as the AES cipher

# Summary

- Finite field arithmetic
- AES structure
  - General structure
  - Detailed structure
- AES key expansion
  - Key expansion algorithm
  - Rationale

- AES transformation functions
  - Substitute bytes
  - ShiftRows
  - MixColumns
  - AddRoundKey
- AES implementation
  - Equivalent inverse cipher
  - Implementation aspects
